Knowledge

Knowledge Items are Antigravity's persistent memory system that automatically captures and organizes important insights, patterns, and solutions from your coding sessions. They help you build upon previous work across conversations.

What is a Knowledge Item?

A Knowledge Item is a collection of related information on a specific topic. Each Knowledge Item contains a title and summary describing what it covers, and a collection of artifacts providing information on the topic. Possible examples of artifacts include automatically generated documentation, code examples, or persistent memories of user instructions.

How are Knowledge Items Generated?

As you interact with the agent, Antigravity automatically analyzes and extracts information from your conversation and uses that information to create new KIs or update existing KIs.

Viewing Knowledge Items

You can view your Knowledge Items in the Antigravity **Agent Manager**.

The screenshot displays the Antigravity Agent Manager interface. On the left, a sidebar contains navigation links: Inbox, Start conversation, Workspaces (with sub-items rocket and snowflakes), Create Three.js Snowflakes, Open Workspace, Playground, Knowledge (selected), Browser, Settings, and Provide Feedback. The main content area is divided into two panels. The left panel, titled 'Knowledge', lists three items: 'Three.js Project Template' (with sub-items Color scheme, Debugging, Vite setup), 'Three.js Rocket Animation' (with sub-items Implementation plan, Index, Main, Style), and 'Three.js Snowflake Animation' (with sub-items Implementation plan, Index, Main, Style). The right panel, titled 'Debugging', shows 'Debugging Common Issues' with a section for 'Failed to resolve import "three"'. It provides a resolution step: '1. Stop the development server.' followed by '2. Install the three dependency by running the following command in your terminal: npm install three'. Below this, it shows '3. Restart the development server: npm run dev'. A 'Missing script: "dev"' section explains an error message and provides a resolution step: '1. Open your package.json file. 2. Ensure it has a scripts section and a devDependencies section with vite. It should look similar to this:'. A code block shows a sample package.json configuration with fields for name, private, version, type, scripts (dev, preview), dependencies (three), and devDependencies (vite).

How are Knowledge Items used by the Agent?
