

Artifacts > Implementation Plan

Implementation Plan

Agent utilizes the implementation plan artifact to architect changes within your codebase to accomplish a task. These plans contain technical details on what revisions are necessary and are meant to be reviewed by the user. Below is an example plan generated by the agent.

Unless you have your artifact review policy set to “Always Proceed” [link to docs on this setting], Agent will typically request your review on the implementation plan before making the changes needed to complete your task. You can click either the in-conversation or artifact header “Proceed” button to instantly continue with Agent’s plan.

Oftentimes, Agent will create a plan that is slightly different from what you exactly want. Antigravity supports commenting on these artifacts so you can provide feedback to Agent for any reason, whether it be to decrease scope of changes, use a different tech stack, or correct any Agent discrepancies.

Artifacts > Implementation Plan

Once you have left comments on the implementation plan, you can still use the “Proceed” to continue with Agent’s plan; alternatively, you can also toggle the “Review” button in the artifact header, where you can examine all comments and leave a message as feedback instead of directly proceeding, if needed.

Once you have proceeded or left a review, Agent will continue its work, either iterating on the implementation plan and re-requesting your review or beginning with its work!

■

Artifacts > Implementation Plan

INDICATOR

Consensus Algorithm: The proposed approach uses weighted averaging based on API reliability scores and confidence intervals. Alternative approaches include:

- Simple median of all forecasts
- Machine learning-based prediction
- Voting system with outlier rejection

Please confirm the preferred approach.

Proposed Changes

Backend Service Layer

[NEW] - server.js

Node.js/Express server that:

- Provides REST API endpoints for weather data
- Handles CORS for frontend requests
- Manages API key security (environment variables)
- Implements rate limiting and caching

[NEW] - services/weather/aggregator.js

Core aggregation service that:

- Retrieves data from multiple weather APIs in parallel
- Normalizes data structures from different providers
- Implements consensus algorithm for forecast accuracy
- Handles API failure gracefully with fallbacks
- Returns unified hourly forecast data (48 hours)

[NEW] - services/weather/providers.js

Individual API integrations:

- OpenWeatherMap: Hourly forecast data
- Open-Meteo: High-resolution hourly forecasts
- WeatherAPI.com: 16-day hourly forecasts
- Standardized response format for each provider
- Error handling and timeout management
